ABSTRACT

An experimental investigation has been conducted to evaluate the entrainment characteristics of a thrust augmenting ejector, with a small, oscillating airfoil inserted in the potential core of the primary jet. Velocity distributions were measured across the width of the jet, at downstream distances of 20 and 40 nozzle widths, with the jet exhausting into still air and with the jet exhausting into an instrumented ejector shroud, for the following range of parameters: Pressure ratio 1.137 and 1.268, amplitude of oscillation 2.6° and 6.9° zero-to-peak, frequency of oscillation 0, 20, 40 and 60 Hz. Static pressure distributions were measured within the shroud when the ejector was installed. The results amplify previously conducted studies. Jet spreading and entrainment appear to increase with increasing amplitude and frequency of oscillation and to decrease with increasing nozzle pressure ratio.

I. INTRODUCTION

In recent years, considerable effort has been directed towards the development of high-performance, fixed-wing aircraft with V/STOL capability. This V/STOL requirement presents an immediate design dilemma; the powerplant and engine inlet must be of sufficient size to produce the large vectored thrust components necessary for vertical takeoff or landing, but small enough to prevent excessive ram drag and weight penalties from being incurred in the fixed-wing mode of operation.

The two operational high-performance V/STOL aircraft, the Soviet YAK-36 and the British-American AV-8B, use the Lift/Lift-Cruise Engine and Thrust Vectoring Nozzle concepts, respectively. Disadvantages of these two concepts include high jet exit velocities and temperatures and excessive fuel consumption.

Another attractive solution to the V/STOL problem is to design the propulsion system for conventional flight and to provide the aircraft with variable geometry thrust augmenting ejectors, which can be faired into the airframe, to boost the available thrust for vertical flight regimes. The Rockwell International XFV-12 utilizes this concept. However, tests to date on the XFV-12 have demonstrated insufficient lift from its thrust augmented wings to provide a VTOL capability.

A thrust augmenting ejector is a device which transfers the energy of a high velocity jet into flow with greatly increased mass, at reduced velocity. A typical ejector construction is diagrammed in figure 1.

The high velocity jet from the primary nozzle is directed into the ejector shroud inlet, where viscous effects, at the edge of the jet, cause mixing and entrainment of the surrounding air. As this flow progresses downstream, a low pressure area is formed within the shroud inlet, thus inducing the secondary flow. The thrust of the device is proportional to the net efflux of momentum at the shroud exit.

When designing ejectors for aircraft applications, many of the physical parameters of the devices, such as ejector length and area ratio, are necessarily constrained by other airframe design considerations. Therefore, recent research in the optimization of ejector performance has focused primarily on increasing the mixing rate of the primary and secondary flows within relatively short, low area ratio ejectors.

The state-of-the-art of thrust augmenting ejectors has been reviewed by Viets [Ref. 1] where details about the hypermixing principle, employed by the XFV-12 ejectors, as well as other promising concepts, can be found. For example, Viets showed that jet oscillation can have a beneficial effect on flow entrainment and he developed several fluidic nozzles to demonstrate this

phenomenon. In general, however, most of the entrainment increasing concepts, discussed in [Ref. 1], involve modification of the primary nozzle, accepting a decrease in nozzle efficiency, in order to increase the overall efficiency of the ejector device.

Platzer and Simmons [Ref. 2] recently suggested a different method for enhancing secondary flow entrainment. A small airfoil, situated in the potential core of the primary jet, was excited into small pitch oscillations such that both frequency and amplitude of oscillation could be varied over a significant range. A first series of results was reported by Simmons et. al. [Ref. 3] for vane excited free-jets using pitot tube and hot wire measurements. Collins et. al. [Ref. 4] provided additional data on the vane excited free-jet utilizing pitot tube, hot wire and laser doppler velocimetry measurements.

It is the objective of the experiments described in the following sections to extend the range of parameters measured by Simmons et. al. and Collins et. al., and to explore the effectiveness of vane excited jets in an actual ejector configuration.

II. APPARATUS

The major components of the experimental apparatus include the plenum chamber, nozzle and ejector shroud.

The plenum chamber is a duplicate of the one used by Collins et. al., as described in [Ref. 4], and it is depicted in figures 2 and 3. Inlet air is provided from a compressor through five one inch flexible tubes in the rear face of the chamber. Two honey-comb flow straighteners are installed as indicated to reduce turbulence. Chamber stagnation pressure and temperature are monitored with a manometer and thermocouple respectively.

Every effort was made to construct the nozzle to provide identical exit conditions to those encountered in the previous experiments. However, the nozzle assembly was modified extensively, from the original flat plate, to one with more suitable aerodynamic fairing for use in an ejector. The nozzle itself remains unchanged, with length $L=300$ mm and width $h=6$ mm. The nozzle assembly is illustrated in figures 4 and 5.

The same vane, which is a symmetric airfoil section, with a thickness of 1.3 mm, a span of 360 mm, and a chord of 10 mm, is located symmetrically, in the potential core, at $1.42h$ from the nozzle. The vane is supported with two bearings, 4.5 mm thick, each, and 123 mm apart, to prevent vane flutter at high nozzle pressure ratios, thereby reducing the nozzle's aspect ratio to an

effective 1:20. Vane and oscillator mechanisms are depicted in figures 2, 3, 6 and 7.

A more complicated vane oscillation mechanism was required to remove the electric motor from the shroud inlet area. Variation in vane deflection amplitude is accomplished by changing the off-center attachment points, or eccentricity (e), of the two cams on the drive shaft. The cams were designed to provide vane amplitude options of 2.6°, 5.2° and 6.9° zero to peak. Adjustment of the turnbuckles on the push-rods is required after each amplitude change to ensure that the vane oscillates about 0° angle of attack.

The vane oscillation frequency is controlled by varying the power output of a DC power supply. Frequency readout is available on a frequency meter which utilizes a magnetic pickup to "count" the passages of six small screws inserted around the circumference of the motor shaft extension sleeve.

Details of the construction of the ejector shroud are provided in figures 8 through 17. Shroud length is fixed at 38 in (152h). Shroud width is 20 in. Although ejector area ratio is variable, and is controlled by adjusting the distance between the top and bottom shroud sections, the height between the sections remained fixed at 5.5 in (23.3h) throughout the experiment.

The shroud is instrumented for measurement of static pressures along the centerline of the bottom shroud section. Figures 15 and

16 diagram the location of the 31 static pressure taps. Figure 17 illustrates the configuration of the pressure taps. A manometer board is used for display of static pressure information.

Pitot tube alignment points along the top section and right side section provide the capability to measure velocity distributions at any cross-section in the shroud in both the horizontal and vertical directions.

A pitot-static tube with hole internal diameter 0.74 mm was used. The tube has four static holes located symmetrically around the periphery at 17 tube diameters from the tip. Identical pneumatic capacitors of volume 500 ml were used in both the total pressure and static pressure lines to dampen fluctuations. Pitot tube output is indicated on a manometer. The pitot tube, as well as the pitot tube alignment stations, are depicted in figure 7.

III. EXPERIMENTAL INVESTIGATION

Two series of velocity measurements were performed. In the first series, the jet exhausted into still air and mean velocity measurements were made across the width of the jet at its midspan, at a distance of 20 and 40 nozzle widths downstream, for the following range of parameters:

Nozzle Pressure Ratio	1.137	1.268
Jet Exit Reynold Number	5.85×10^4	8.19×10^4
Vane Amplitude of Oscillation	2.6°	6.9° zero-to-peak
Vane Frequency of Oscillation	0, 20, 40, 60 HZ	

In the second series of velocity measurements, the constant area ejector shroud was mounted symmetrically, with the nozzle exit plane flush with the shroud inlet plane. Again, mean velocity measurements were made across the ejector height, at its midspan, at distances of 20 and 40 nozzle widths downstream for the same range of parameters. In addition, shroud static pressure distributions were measured, with the nozzle and shroud in the same configuration, for the same range of parameters.

IV. RESULTS

Mean centerline velocity distributions are plotted in figures 18 through 23 for the vane excited free-jet operating at pressure ratios 1.137 and 1.268, vane amplitudes of 2.6° and 6.9° zero to peak, and frequencies of oscillation of 0, 20, 40, and 60 HZ. Tables 1 through 23 give detailed tabulations of these distributions.

The mean velocity distributions at the mid-span of the ejector are plotted in figures 24 through 31. These distributions are tabulated in tables 24 through 48.

Static pressure distributions at the mid-span of the ejector are shown in figures 32 through 35 and are tabulated in tables 49 through 62.

The free-jet and jet with ejector shroud velocity profiles were integrated to provide data for mean entrainment calculations. In order to provide a uniform method of integration, the free-jet curves were arbitrarily terminated at the points on the horizontal axis where the value for U/U_0 decreased to 0.1. The curves from the ejector measurements were integrated from wall to wall. Tabulations of the mean entrainment calculations, where mean entrainment is defined as $[Q(x)/Q_E - 1]$, are provided in tables 63 and 64.

V. DISCUSSION

The free jet velocity distributions plotted in figures 18 through 23 show several consistent trends. The vane oscillation produces a substantial spreading of the jet which is accompanied by a much faster center velocity decay than is obtained for the steady jet. The effect of vane frequency of oscillation is seen to produce increased spreading with increasing frequency, at least up to the highest measured frequency (60 HZ). Also, as one would expect, the spreading increases with increasing vane amplitude, but decreases with increasing pressure ratio. The present results then confirm the earlier measurements by Simmons et. al. [Ref. 3], which were obtained for a rather low pressure ratio and add new information about the effect of pressure ratio and also extend the frequency range. The present trends are also in agreement with the measurements by Collins et. al. [Ref. 4].

The velocity distributions, figures 24-31, measured in the constant area ejector at 20 and 40 nozzle widths downstream show again the effectiveness of vane oscillation on jet spreading. While little effect is visible at 20 nozzle widths at the smaller vane amplitude (2.6°), the larger amplitude (6.9°) produces a quite significant effect already at 20 nozzle widths. The effect of vane oscillation is again seen quite clearly for both vane amplitudes. In fact, for the larger amplitude a rather flat distribution is already produced.

The vane effectiveness is further corroborated by the static pressure distributions. Greater suction peaks are seen to occur at the well-rounded ejector inlet with increasing vane amplitude and frequency, figures 32 through 35.

VI. CONCLUSIONS AND RECOMMENDATIONS

Jet excitation by an oscillating vane situated in the jet's potential core produces increased jet spreading and hence secondary flow entrainment for the two measured pressure ratios. This method therefore may have applications in thrust augmenting aircraft ejectors where weight and volume need to be minimized. More detailed measurements, especially at higher pressure ratios, should be performed in order to assess the potential of this jet mixing device.

TABLE 63

MEAN ENTRAINMENT DATA (FREE JET)

TABULATED VALUES FOR $[Q(x)/Q_p - 1]$

PRESSURE RATIO 1.137

VANE AMPLITUDE 2.6° ZERO-PEAK

FREQUENCY (HZ)	0	20	40	60
PITOT LOCATION				
20 NOZZLE WIDTHS	1.77	1.89	1.96	1.97
40 NOZZLE WIDTHS	3.00	3.17	3.33	3.63

VANE AMPLITUDE 6.9° ZERO-PEAK

FREQUENCY (HZ)	0	20	40	60
PITOT LOCATION				
20 NOZZLE WIDTHS	1.77	2.35	2.45	2.55
40 NOZZLE WIDTHS	3.00	3.84	4.29	4.66

PRESSURE RATIO 1.268

VANE AMPLITUDE 2.6° ZERO-PEAK

FREQUENCY (HZ)	0	20	40	60
PITOT LOCATION				
20 NOZZLE WIDTHS	1.84	1.89	1.87	1.93
40 NOZZLE WIDTHS	---	---	---	---

VANE AMPLITUDE 6.9° ZERO-PEAK

FREQUENCY (HZ)	0	20	40	60
PITOT LOCATION				
20 NOZZLE WIDTHS	1.84	2.36	2.39	2.42
40 NOZZLE WIDTHS	---	---	4.31	4.50

TABLE 64

MEAN ENTRAINMENT DATA (EJECTOR INSTALLED)

TABULATED VALUE FOR $[Q(X)/Q_E - 1]$

PRESSURE RATIO 1.137

VANE AMPLITUDE 2.6° ZERO-PEAK

FREQUENCY (HZ)	0	20	40	60
PITOT LOCATION				
20 NOZZLE WIDTHS	4.19	4.42	4.54	4.57
40 NOZZLE WIDTHS	5.71	5.79	5.85	5.88

VANE AMPLITUDE 6.9° ZERO-PEAK

FREQUENCY (HZ)	0	20	40	60
PITOT LOCATION				
20 NOZZLE WIDTHS	4.19	4.83	4.97	5.03
40 NOZZLE WIDTHS	5.71	6.08	6.13	6.16

PRESSURE RATIO 1.268

VANE AMPLITUDE 2.6° ZERO-PEAK

FREQUENCY (HZ)	0	20	40	60
PITOT LOCATION				
20 NOZZLE WIDTHS	4.74	4.99	5.04	5.09
40 NOZZLE WIDTHS	6.71	---	---	---

VANE AMPLITUDE 6.9° ZERO-PEAK

FREQUENCY (HZ)	0	20	40	60
PITOT LOCATION				
20 NOZZLE WIDTHS	4.74	5.14	5.28	5.33
40 NOZZLE WIDTHS	6.71	6.83	6.90	6.93
